

## **CIVITAS** indicators

Public transport connectivity index – Version 2 (TRA\_PT\_PTC2)

### **DOMAIN**

Environment

Energy

Society

Economy

**TOPIC** 

**Public transport** 

**IMPACT** 

**Public transport connectivity** 

Improving the connectivity of public transport

TRA PT

### **Category**

Key indicator

Supplementary indicator

State indicator

### **CONTEXT AND RELEVANCE**

Public transport is generally more environmental-friendly than motorised private transport because it facilitates the efficient use of resources by transporting a larger number of passengers in a single vehicle, thereby reducing overall energy consumption and emissions per person compared to individual private vehicles. It is therefore desirable that public transport is widely used. A requirement for the use of public transport is its connectivity: if a limited number of destinations can be reached, especially within a reasonable time, public transport cannot be an attractive or even feasible option for personal urban trips.

This indicator provides a measure of the connectivity of public transport. It is a relevant indicator when the policy action is aimed at improving the number of destinations reachable by public transport considering a specific area of the city as the starting point, without changing public transport line (i.e., directly, no connections). A successful action is reflected in a <u>HIGHER</u> value of the indicator.

### **DESCRIPTION**

This indicator is the **number of stops and stations** that can be reached using public transport from one stop or station of the experiment area **without changing public transport line**. The unit of measurement of the indicator is the **number of stops and stations**.

### METHOD OF CALCULATION AND INPUTS

The indicator should be calculated exogenously, building on a set of required inputs, and then coded in the supporting tool.

# Method Calculation of the index based on PT timetables and stops Significance: 0.50

### **INPUTS**

The following information is needed to compute the indicator:

- a) A map of the public transport stops and stations in the city.
- b) The timetable of public transport services available from stops/stations in the experiment area

The experiment would be reflected in the indicator by changing the timetable of public transport services available from stops/stations in the experiment area as result of e.g., addition of one route, modification of the routes, addition of a stop, etc.

#### METHOD OF CALCULATION

The indicator is simply computed by counting the number of stops and station that can be reached from the experiment area without requiring a transfer. This is determined based on the timetable of the public transport services and the map of stops and stations of the city.

### **EQUATIONS**

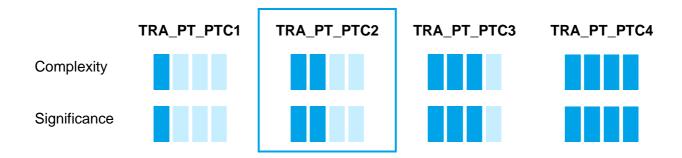

The quantification of this indicator does not require any equation. The value of the indicator *PTConnIndex* to be coded in the supporting tool is just the observed number of stops and station that can be reached from the experiment area without requiring a transfer.

### **ALTERNATIVE INDICATORS**

Alternative indicators for measuring the same impact in the experiment area include **TRA\_PT\_PTC1**, **TRA\_PT\_PTC3**, and **TRA\_PT\_PTC4**.

TRA\_PT\_PTC1 is the simplest and least significant indicator for assessing public transport connectivity, as it merely counts the number of public transport lines with stops in the experiment area. Meanwhile, TRA\_PT\_PTC3 provides a more comprehensive measure by considering the number of stops and stations reachable within 20 minutes from any stop or station in the experiment area. This makes it a more meaningful indicator in comparison to of TRA\_PT\_PTC2, which only accounts for direct trips without connections.

TRA\_PT\_PTC4 is the most complex but also the most meaningful. In addition to evaluating the supply of public transport in the experiment area, it also considers whether key urban functions—such as offices, educational institutions, healthcare facilities, grocery stores, and recreational spaces—are effectively connected by public transport. By accounting for the spatial distribution of services, TRA\_PT\_PTC4 offers a more comprehensive view of accessibility. However, its calculation is more demanding, requiring detailed spatial data on service locations.

If the experiment area is the whole city, there are three alternative indicators to measure PT connectivity: TRA\_PT\_PTC5, TRA\_PT\_PTC6, TRA\_PT\_PTC7. These three indicators are of growing complexity and significance.

It should also be noted that public transport connectivity is one of the three components of **TRA\_FC\_AC1**. This indicator combines public transport connectivity, bike connectivity and road congestion to assess overall accessibility. The online tool automatically computes **TRA\_FC\_AC1** if the three sub-indicators have been calculated.
