TOPIC

Freight

IMPACT

Compliance with local policy

Increased readiness of freight operators to comply with local freight access policies through the adoption of policy-aware digital planning tools.

CONTEXT AND RELEVANCE

The effectiveness of urban freight access policies, such as low- and zero-emission zones, delivery time windows, and vehicle weight or size restrictions, increasingly depends on how well these rules are integrated into operators' route-planning processes. Digital planning and routing tools are now standard in the logistics sector, and keeping local policy data up to date within these systems enables operators to develop routes that are both efficient and compliant with the access conditions in force.

This indicator measures the share of freight operators using a digital planning/routing tool that incorporates the local freight access policies currently in force within the pilot area. **It is a relevant indicator when the policy action aims to increase freight operators' digital readiness to comply with local freight access policies. A successful action is reflected in a HIGHER value of the indicator after the experiment compared to the BAU case.**

DESCRIPTION

The indicator assesses whether freight operators' digital planning and routing tools have been configured or updated to reflect the local freight access policies currently in force in the pilot city, such as low- and zero-emission zone boundaries, delivery time windows, and vehicle weight or size restrictions.

The indicator is expressed as a **percentage (%)**.

METHOD OF CALCULATION AND INPUTS

The indicator should be calculated **exogenously**. The user computes the indicator value outside the CIVITAS Evaluation tool according to the method described below and enters the final result into the tool.

Method 1	
Survey delivery companies	Significance: 0.50 
INPUTS The following information is needed to compute the indicator: • The total number of logistics operators surveyed in the pilot city. • The number of surveyed operators using a digital planning/routing tool which incorporates up-to-date local freight access policies.	
EQUATIONS The equation that should be applied to quantify the indicator is: $ShPAT = \frac{PAT}{Op} * 100$	

Where:

$ShPAT$ = Share of operators using policy-aware digital planning tools (%)

PAT = Number of surveyed logistics operators using a digital planning/routing tool which incorporates local freight access policies currently in force

OP = Total number of logistics operators surveyed in the pilot city
