CONTEXT AND RELEVANCE

Motorised freight transport refers to the movement of goods using motor vehicles such as trucks and vans. This mode of transport is widely used to deliver goods to customers in urban areas, but it contributes significantly to energy consumption, emissions, noise, and space occupancy. These factors negatively impact environmental sustainability and quality of life in cities.

Alternative solutions for urban deliveries, such as cargo bikes, parcel lockers and drop-off points, autonomous bots, drones, and shared logistics, can help reduce the reliance on conventional motorized freight transport. These alternatives contribute to lower emissions, reduced noise pollution, and improved space efficiency in urban areas.

This indicator provides a measure of the share of deliveries made by cargo bikes in the experiment area. **This indicator is relevant when the policy action aims to increase adoption of cargo bikes by logistics providers for delivering goods in the pilot area. A successful action is reflected in a HIGHER value of the indicator.**

DESCRIPTION

The indicator is the **share of deliveries made by cargo bikes in the experiment area**.

The indicator is expressed as a **percentage (%)**.

METHOD OF CALCULATION AND INPUTS

The indicator should be computed exogenously, by applying the method described and then coded in the supporting tool.

Method 1		
Calculation based on data from logistics operators	Significance: 0.75	
INPUTS The following information is needed to compute the indicator: a) The number of deliveries made by cargo bikes by logistics providers in the experiment area over a reference period b) The total number of deliveries made by logistics providers in the experiment area over the same reference period The experiment would result in a modification in the number of deliveries by cargo bikes.		
METHOD OF CALCULATION The indicator should be computed exogenously according to the following steps: • Retrieval of the number of deliveries by cargo bikes and the total number of deliveries in the experiment area. If in the 'before' scenario no cargo bikes are used for deliveries in the experiment area, this value equals zero. The data should be		

obtained from the logistics operators active in the pilot area and should cover a relevant time period, such as an 'average day' reflecting normal operations.

- **Calculation of the index** by computing the ratio between the number of cargo bike deliveries and the total number of deliveries in the pilot area.

EQUATIONS

The equation computing the index is the following:

$$CBIndex = \frac{CBDel}{TotDel} \times 100$$

Where:

CBDel = Number of deliveries by cargo bikes in the experiment area over a reference period

TotDel = Total number of deliveries in the experiment area over the same reference period

ALTERNATIVE INDICATORS

This indicator measures the share of deliveries completed from microhubs. To assess the adoption of other innovative last-mile delivery solutions, the framework provides indicator **TRA_FR_IL2** for the share of deliveries made by autonomous bots, **TRA_FR_IL3** for the share of deliveries made by drones, and **TRA_FR_IL4** for the share of deliveries made from microhubs.
